Generic YANG Data Model for the Management of Operations, Administration, and Maintenance (OAM) Protocols That Use Connectionless Communications

Abstract

This document presents a base YANG Data model for the management of Operations, Administration, and Maintenance (OAM) protocols that use connectionless communications. The data model is defined using the YANG data modeling language, as specified in RFC 7950. It provides a technology-independent abstraction of key OAM constructs for OAM protocols that use connectionless communication. The base model presented here can be extended to include technology-specific details.

There are two key benefits of this approach: First, it leads to uniformity between OAM protocols. Second, it supports both nested OAM workflows (i.e., performing OAM functions at the same level or different levels through a unified interface) as well as interactive OAM workflows (i.e., performing OAM functions at the same level through a unified interface).

Status of This Memo

This is an Internet Standards Track document.

This document is a product of the Internet Engineering Task Force (IETF). It represents the consensus of the IETF community. It has received public review and has been approved for publication by the Internet Engineering Steering Group (IESG). Further information on Internet Standards is available in Section 2 of RFC 7841.

Information about the current status of this document, any errata, and how to provide feedback on it may be obtained at https://www.rfc-editor.org/info/rfc8532.

[Page 2]

1. Introduction

Operations, Administration, and Maintenance (OAM) are important networking functions that allow operators to:

- 1. monitor network communications (i.e., reachability verification and Continuity Check)
- 2. troubleshoot failures (i.e., fault verification and localization)
- 3. monitor service-level agreements and performance (i.e., performance management)

An overview of OAM tools is presented in [RFC7276].

Ping and Traceroute (see [RFC792] and [RFC4443]) are respectively well-known fault verification and isolation tools for IP networks. Over the years, different technologies have developed similar toolsets for equivalent purposes.

The different sets of OAM tools may support both connection-oriented or connectionless technologies. In connection-oriented technologies, a connection is established prior to the transmission of data. After the connection is established, no additional control information such as signaling or operations and maintenance information is required to transmit the actual user data. In connectionless technologies, data is typically sent between communicating endpoints without prior arrangement, but control information is required to identify the destination (e.g., [G.800] and [RFC7276]). The YANG data model for OAM protocols using connection-oriented communications is specified in [RFC8531].

This document defines a base YANG data model for OAM protocols that use connectionless communications. The data model is defined using the YANG data modeling language [RFC7950]. This generic YANG data model for connectionless OAM includes only configuration and state data. It can be used in conjunction with the data retrieval method model described in [RFC8533], which focuses on the data retrieval procedures such as RPC, or it can be used independently of this data retrieval method model.

RFC 8532 Connectionless OAM YANG Data Model April 2019

2. Conventions Used in This Document

The following terms are defined in [RFC6241] and are used in this specification:

- o client
- o configuration data
- o server
- o state data

The following terms are defined in [RFC7950] and are used in this specification:

- o augment
- o data model
- o data node

The terminology for describing YANG data models is found in [RFC7950].

- 2.1. Abbreviations
 - BFD Bidirectional Forwarding Detection [RFC5880].
 - RPC Remote Procedure Call [RFC1831].
 - DSCP Differentiated Services Code Point.
 - VRF Virtual Routing and Forwarding [RFC4382].
 - OWAMP One-Way Active Measurement Protocol [RFC4656].
 - TWAMP Two-Way Active Measurement Protocol [RFC5357].
 - AS Autonomous System.
 - LSP Label Switched Path.
 - TE Traffic Engineering.
 - MPLS Multiprotocol Label Switching.
 - NI Network Instance.

Kumar, et al. Standards Track

[Page 4]

PTP - Precision Time Protocol [IEEE.1588v2].

NTP - Network Time Protocol [RFC5905].

2.2. Terminology

MAC - Media Access Control.

MAC address - Address for the data-link layer interface.

TP - Test Point. The TP is a functional entity that is defined at a node in the network and can initiate and/or react to OAM diagnostic tests. This document focuses on the data-plane functionality of TPs.

RPC operation - A specific Remote Procedure Call.

CC - A Continuity Check [RFC7276] is used to verify that a destination is reachable and therefore also referred to as reachability verification.

2.3. Tree Diagrams

Tree diagrams used in this document follow the notation defined in [RFC8340].

3. Overview of the Connectionless OAM Model

The YANG data model for OAM protocols that use connectionless communications has been split into two modules:

- o The "ietf-lime-time-types" module provides common definitions such as Time-related data types and Timestamp-related data types.
- o The "ietf-connectionless-oam" module defines technologyindependent abstraction of key OAM constructs for OAM protocols that use connectionless communication.

The "ietf-connectionless-oam" module augments the "/networks/network/ node" path defined in the "ietf-network" module [RFC8345] with the 'test-point-locations' grouping defined in Section 3.5. The network nodes in the "/networks/network/node" path are used to describe the network hierarchies and the inventory of nodes contained in a network.

Under the 'test-point-locations' grouping, each test point location is chosen based on the 'tp-location-type' leaf, which, when chosen, leads to a container that includes a list of 'test-point-locations'.

Kumar, et al. Standards Track [Page 5] Each 'test-point-locations' list includes a 'test-point-locationinfo' grouping. The 'test-point-location-info' grouping includes:

- o 'tp-technology' grouping,
- o 'tp-tools' grouping, and
- o 'connectionless-oam-tps' grouping.

The groupings of 'tp-address' and 'tp-address-ni' are kept out of the 'test-point-location-info' grouping to make it addressing agnostic and allow varied composition. Depending upon the choice of the 'tp-location-type' (determined by the 'tp-address-ni'), each container differs in its composition of 'test-point-locations', while the 'test-point-location-info' is a common aspect of every 'test-point-locations'.

The 'tp-address-ni' grouping is used to describe the corresponding network instance. The 'tp-technology' grouping indicates OAM technology details. The 'connectionless-oam-tps' grouping is used to describe the relationship of one test point with other test points. The 'tp-tools' grouping describes the OAM tools supported.

In addition, at the top of the model, there is an 'cc-oper-data' container for session statistics. A grouping is also defined for common session statistics, and these are only applicable for proactive OAM sessions (see Section 3.2).

3.1. TP Address

With connectionless OAM protocols, the TP address can be one of the following types:

- o MAC address [RFC6136] at the data-link layer for TPs
- o IPv4 or IPv6 address at the IP layer for TPs
- o TP-attribute identifying a TP associated with an application-layer function
- o Router-id to represent the device or node, which is commonly used to identify nodes in routing and other control-plane protocols [RFC8294].

To define a forwarding treatment of a test packet, the 'tp-address' grouping needs to be associated with additional parameters, e.g., DSCP for IP or Traffic Class [RFC5462] for MPLS. In the generic

Kumar, et al. Standards Track [Page 6]

connectionless OAM YANG data model, these parameters are not explicitly configured. The model user can add corresponding parameters according to their requirements.

3.2. Tools

The different OAM tools may be used in one of two basic types of activation: proactive and on-demand. Proactive OAM refers to OAM actions that are carried out continuously to permit proactive reporting of faults. The proactive OAM method requires persistent configuration. On-demand OAM refers to OAM actions that are initiated via manual intervention for a limited time to carry out specific diagnostics. The on-demand OAM method requires only transient configuration (e.g., [RFC7276] and [G.8013]). In connectionless OAM, the 'session-type' grouping is defined to indicate which kind of activation will be used by the current session.

In connectionless OAM, the tools attribute is used to describe a toolset for fault detection and isolation. In addition, it can serve as a constraint condition when the base model is extended to a specific OAM technology. For example, to fulfill the ICMP PING configuration, the "../coam:continuity-check" leaf should be set to "true", and then the LIME base model should be augmented with details specific to ICMP PING.

3.3. OAM Neighboring Test Points

Given that typical network communication stacks have a multi-layer architecture, the set of associated OAM protocols has also a multilayer structure; each communication layer in the stack may have its own OAM protocol [RFC7276] that may also be linked to a specific administrative domain. Management of these OAM protocols will necessitate associated test points in the nodes accessible by appropriate management domains. Accordingly, a given network interface may actually present several test points.

Each OAM test point may have an associated list of neighboring test points that are in other layers up and down the protocol stack for the same interface and are therefore related to the current test point. This allows users to easily navigate between related neighboring layers to efficiently troubleshoot a defect. In this model, the 'position' leaf defines the relative position of the neighboring test point corresponding to the current test point, and it is provided to allow correlation of faults at different locations. If there is one neighboring test point placed before the current test point, the 'position' leaf is set to -1. If there is one neighboring

Kumar, et al. Standards Track

[Page 7]

test point placed after the current test point, the 'position' leaf is set to 1. If there is no neighboring test point placed before or after the current test point, the 'position' leaf is set to 0.

+ oam-neighboring-tps* [index]	
+ index?	uint16
+ position?	int8
+ (tp-location)?	
+:(mac-address)	
+ mac-address-location?	yang:mac-address
+:(ipv4-address)	
+ ipv4-address-location?	inet:ipv4-address
+:(ipv6-address)	
+ ipv6-address-location?	inet:ipv6-address
+: (as-number)	
+ as-number-location?	inet:as-number
+:(router-id)	
+ router-id-location?	rt:router-id

^{3.4.} Test Point Location Information

This is a generic grouping for Test Point Location Information (i.e., 'test-point-location-info' grouping). It provides details of Test Point Location using the 'tp-technology', 'tp-tools', and 'oam-neighboring-tps' groupings, all of which are defined above.

3.5. Test Point Locations

This is a generic grouping for Test Point Locations. 'tp-locationtype' leaf is used to define location types -- for example, 'ipv4-location-type', 'ipv6-location-type', etc. Container is defined under each location type containing a list keyed to a test point address, Test Point Location Information defined in the section above, and network instance name (e.g., VRF instance name) if required.

3.6. Path Discovery Data

This is a generic grouping for the path discovery data model that can be retrieved by any data retrieval method, including RPC operations. Path discovery data output from methods, includes 'src-test-point' container, 'dst-test-point' container, 'sequence-number' leaf, 'hop-cnt' leaf, session statistics of various kinds, and information related to path verification and path trace. Path discovery includes data to be retrieved on a 'per-hop' basis via a list of 'path-traceinfo-list' items which includes information such as 'timestamp' grouping, 'ingress-intf-name', 'egress-intf-name', and 'app-metadata'. The path discovery data model is made generic enough to allow

Kumar, et al. Standards Track

[Page 8]

different methods of data retrieval. None of the fields are made mandatory for that reason. Note that a set of retrieval methods are defined in [RFC8533].

3.7. Continuity Check Data

This is a generic grouping for the Continuity Check data model that can be retrieved by any data retrieval methods including RPC operations. Continuity Check data output from methods, includes 'src-test-point' container, 'dst-test-point' container, 'sequence-number' leaf, 'hop-cnt' leaf, and session statistics of various kinds. The Continuity Check data model is made generic enough to allow different methods of data retrieval. None of the fields are made mandatory for that reason. Noted that a set of retrieval methods are defined in [RFC8533].

3.8. OAM Data Hierarchy

6. Connectionless Model Applicability

The "ietf-connectionless-oam" module defined in this document provides a technology-independent abstraction of key OAM constructs for OAM protocols that use connectionless communication. This module can be further extended to include technology-specific details, e.g., adding new data nodes with technology-specific functions and parameters into proper anchor points of the base model, so as to develop a technology-specific connectionless OAM model.

This section demonstrates the usability of the connectionless YANG OAM data model to various connectionless OAM technologies, e.g., BFD and LSP ping. Note that, in this section, several snippets of technology-specific model extensions are presented for illustrative purposes. The complete model extensions should be worked on in the working groups of the respective protocols.

Standards Track [Page 44] Kumar, et al.

6.1. BFD Extension

RFC 7276 defines BFD as a connection-oriented protocol. It is used to monitor a connectionless protocol in the case of basic BFD for IP.

6.1.1. Augment Method

The following sections show how the "ietf-connectionless-oam" module can be extended to cover BFD technology. For this purpose, a set of extensions are introduced such as the technology-type extension and test-point attributes extension.

Note that a dedicated BFD YANG data model [BFD-YANG] is also standardized. Augmentation of the "ietf-connectionless-oam" module with BFD-specific details provides an alternative approach with a unified view of management information across various OAM protocols. The BFD-specific details can be the grouping defined in the BFD model, thereby avoiding duplication of effort.

6.1.1.1. Technology-Type Extension

No BFD technology type has been defined in the "ietf-connectionlessoam" module. Therefore, a technology-type extension is required in the module extension.

The snippet below depicts an example of adding the "bfd" type as an augment to the "ietf-connectionless-oam" module:

```
augment "/nd:networks/nd:network/nd:node/"
+"coam:location-type/coam:ipv4-location-type"
+"/coam:test-point-ipv4-location-list/"
+"coam:test-point-locations/coam:technology"
{
   leaf bfd{
  type string;
  }
}
```

6.1.1.2. Test Point Attributes Extension

To support BFD, the "ietf-connectionless-oam" module can be extended by adding specific parameters into the "test-point-locations" list and/or adding a new location type such as "BFD over MPLS TE" under "location-type".

Kumar, et al. Standards Track

[Page 45]

6.1.1.2.1. Define and Insert New Nodes into Corresponding test-pointlocation

In the "ietf-connectionless-oam" module, multiple "test-pointlocation" lists are defined under the "location-type" choice node. Therefore, to derive a model for some BFD technologies (such as IP single-hop, IP multihop, etc.), data nodes for BFD-specific details need to be added to the corresponding "test-point-locations" list. In this section, some groupings that are defined in [BFD-YANG] are reused as follows.

The snippet below shows how the "ietf-connectionless-oam" module can be extended to support "BFD IP Single-Hop":

```
augment "/nd:networks/nd:network/nd:node/"
+"coam:location-type/coam:ipv4-location-type"
+"/coam:test-point-ipv4-location-list/"
       +"coam:test-point-locations"
{
        container session-cfg {
          description "BFD IP single-hop session configuration";
          list sessions {
            key "interface dest-addr";
            description "List of IP single-hop sessions";
            leaf interface {
              type if:interface-ref;
              description
                "Interface on which the BFD session is running.";
            }
            leaf dest-addr {
             type inet:ip-address;
             description "IP address of the peer";
            }
           uses bfd:bfd-grouping-common-cfg-parms;
           uses bfd:bfd-grouping-echo-cfg-parms;
          }
        }
}
```

Similar augmentations can be defined to support other BFD technologies such as BFD IP Multihop, BFD over MPLS, etc.

Kumar, et al. Standards Track

[Page 46]

6.1.1.2.2. Add New location-type Cases

In the "ietf-connectionless-oam" module, If there is no appropriate "location-type" case that can be extended, a new "location-type" case can be defined and inserted into the "location-type" choice node.

Therefore, there is flexibility -- the module user can add "locationtype" to support other types of test point that are not defined in the "ietf-connectionless-oam" module. In this section, a new "location-type" case is added, and some groupings that are defined in [BFD-YANG] are reused as follows.

The snippet below shows how the "ietf-connectionless-oam" module can be extended to support "BFD over MPLS-TE":

```
augment "/nd:networks/nd:network/nd:node/coam:location-type"{
case te-location{
 list test-point-location-list{
  key "tunnel-name";
  leaf tunnel-name{
   type leafref{
path "/te:te/te:tunnels/te:tunnel/te:name";
}
description
"Point to a TE instance.";
 }
   uses bfd:bfd-grouping-common-cfg-parms;
       uses bfd-mpls:bfd-encap-cfq;
 }
}
}
```

Similar augmentations can be defined to support other BFD technologies such as BFD over LAG, etc.

6.1.2. Schema Mount

An alternative method is using the schema mount mechanism [RFC8528] in the "ietf-connectionless-oam" module. Within the "test-pointlocations" list, a "root" attribute is defined to provide a mount point for models that will be added onto per "test-point-locations". Therefore, the "ietf-connectionless-oam" module can provide a place in the node hierarchy where other OAM YANG data models can be attached, without any special extension in the "ietf-connectionlessoam" YANG data module [RFC8528]. Note that the limitation of the schema mount method is that it's not allowed to specify certain modules that are required to be mounted under a mount point.

Kumar, et al. Standards Track

[Page 47]

The snippet below depicts the definition of the "root" attribute. anydata root { yangmnt:mount-point root; description "Root for models that are supported per test point"; } The following section shows how the "ietf-connectionless-oam" module can use schema mount to support BFD technology. 6.1.2.1. BFD Modules Might Be Populated in schema-mounts To support BFD technology, "ietf-bfd-ip-sh" and "ietf-bfd-ip-mh" YANG modules might be populated in the "schema-mounts" container: <schema-mounts xmlns="urn:ietf:params:xml:ns:yang:ietf-yang-schema-mount"> <mount-point> <module> ietf-connectionless-oam </module> <name>root</name> <use-schema> <name>root</name> </use-schema> </mount-point> <schema> <name>root</name> <module> <name>ietf-bfd-ip-sh </name> <revision>2016-07-04</revision> <namespace> urn:ietf:params:xml:ns:yang:ietf-bfd-ip-sh </namespace> <conformance-type>implement</conformance-type> </module> <module> <name>ietf-bfd-ip-mh</name> <revision> 2016-07-04</revision> <namespace> urn:ietf:params:xml:ns:yang:ietf-bfd-ip-mh </namespace> <conformance-type>implement</conformance-type> </module> </schema> </schema-mounts>

Kumar, et al.

Standards Track

[Page 48]

```
and the "ietf-connectionless-oam" module might have:
<ietf-connectionless-oam
uri="urn:ietf:params:xml:ns:yang:ietf-connectionless-oam">
   . . . . . .
 <test-point-locations>
 <ipv4-location>192.0.2.1</ipv4-location>
   . . . . . .
  <root>
   <ietf-bfd-ip-sh uri="urn:ietf:params:xml:ns:yang:ietf-bfd-ip-sh">
    <ip-sh>
    foo
     . . . . . .
    </ip-sh>
   </ietf-bfd-ip-sh>
   <ietf-bfd-ip-mh uri="urn:ietf:params:xml:ns:yang:ietf-bfd-ip-mh">
    <ip-mh>
    foo
     . . . . . .
    </ip-mh>
   </ietf-bfd-ip-mh>
  </root>
 </test-point-locations>
</ietf-connectionless-oam>
```

6.2. LSP Ping Extension

6.2.1. Augment Method

The following sections show how the "ietf-connectionless-oam" module can be extended to support LSP ping technology. For this purpose, a set of extensions are introduced such as the "technology-type" extension and the test-point "attributes" extension.

Note that an LSP Ping YANG data model is being specified [LSP-PING-YANG]. As with BFD, users can choose to use the "ietf-connectionless-oam" as the basis and augment the "ietf-connectionless-oam" model with details specific to LSP Ping in the model extension to provide a unified view across different technologies. The details that are specific to LSP Ping can be the grouping defined in the LSP ping model to avoid duplication of effort.

6.2.1.1. Technology-Type Extension

No LSP Ping technology type has been defined in the "ietf-connectionless-oam" module. Therefore, a technology-type extension is required in the module extension.

Kumar, et al. Standards Track [Page 49]

```
The snippet below depicts an example of augmenting
"ietf-connectionless-oam" with "lsp-ping" type:
augment "/nd:networks/nd:network/nd:node/"
```

```
+"coam:location-type/coam:ipv4-location-type"
+"/coam:test-point-ipv4-location-list/"
       +"coam:test-point-locations/coam:technology"
{
  leaf lsp-ping{
  type string;
 }
}
```

6.2.1.2. Test Point Attributes Extension

To support LSP Ping, the "ietf-connectionless-oam" module can be extended and parameters specific to LSP Ping can be defined and put on the "test-point-locations" list.

Users can reuse the attributes or groupings that are defined in [LSP-PING-YANG] as follows:

The snippet below depicts an example of augmenting the "test-pointlocations" list with LSP Ping attributes:

```
augment "/nd:networks/nd:network/nd:node/"
+"coam:location-type/coam:ipv4-location-type"
+"/coam:test-point-ipv4-location-list/"
        +"coam:test-point-locations"
{
list lsp-ping {
        key "lsp-ping-name";
         leaf lsp-ping-name {
         type string {
           length "1..31";
        }
        mandatory "true";
        description "LSP Ping test name.";
        . . . . . .
      }
```

6.2.2. Schema Mount

An alternative method is using the schema mount mechanism [RFC8528] in the "ietf-connectionless-oam" module. Within the "test-pointlocations" list, a "root" attribute is defined to provide a mounted point for models mounted per "test-point-locations". Therefore, the "ietf-connectionless-oam" model can provide a place in the node

Kumar, et al. Standards Track

[Page 50]

hierarchy where other OAM YANG data models can be attached, without any special extension in the "ietf-connectionless-oam" YANG data module [RFC8528]. Note that the limitation of the schema mount method is that it's not allowed to specify certain modules that are required to be mounted under a mount point.

The snippet below depicts the definition of "root" attribute.

anydata root { yangmnt:mount-point root; description "Root for models supported per test point"; }

The following section shows how the "ietf-connectionless-oam" module can use schema mount to support LSP Ping technology.

6.2.2.1. LSP Ping Modules Might Be Populated in schema-mounts

To support LSP Ping technology, the "ietf-lsp-ping" YANG module [LSP-PING-YANG] might be populated in the "schema-mounts" container:

```
<schema-mounts
   xmlns="urn:ietf:params:xml:ns:yang:ietf-yang-schema-mount">
  <mount-point>
   <module> ietf-connectionless-oam </module>
    <name>root</name>
   <use-schema>
     <name>root</name>
    </use-schema>
  </mount-point>
  <schema>
    <name>root</name>
    <module>
     <name>ietf-lsp-ping </name>
      <revision>2016-03-18</revision>
      <namespace>
       urn:ietf:params:xml:ns:yang: ietf-lsp-ping
      </namespace>
      <conformance-type>implement</conformance-type>
    </module>
  </schema>
</schema-mounts>
```

Kumar, et al.

Standards Track

[Page 51]

```
and the "ietf-connectionless-oam" module might have:
<ietf-connectionless-oam
uri="urn:ietf:params:xml:ns:yang:ietf-connectionless-oam">
   . . . . . .
 <test-point-locations>
 <ipv4-location> 192.0.2.1</ipv4-location>
   . . . . . .
  <root>
   <ietf-lsp-ping uri="urn:ietf:params:xml:ns:yang:ietf-lsp-ping">
    <lsp-pings>
    foo
     . . . . . .
    </lsp-pings>
   </ietf-lsp-ping>
  </root>
 </test-point-locations>
</ietf-connectionless-oam>
```

7. Security Considerations

The YANG module specified in this document defines a schema for data that is designed to be accessed via network management protocols such as NETCONF [RFC6241] or RESTCONF [RFC8040]. The lowest NETCONF layer is the secure transport layer, and the mandatory-to-implement secure transport is Secure Shell (SSH) [RFC6242]. The lowest RESTCONF layer is HTTPS, and the mandatory-to-implement secure transport is TLS [RFC8446].

The NETCONF Configuration Access Control Model (NACM) [RFC8341] provides the means to restrict access for particular NETCONF or RESTCONF users to a preconfigured subset of all available NETCONF or RESTCONF protocol operations and content.

There are a number of data nodes defined in this YANG module that are writable/creatable/deletable (i.e., config true, which is the default). These data nodes may be considered sensitive in some network environments. Write operations (e.g., edit-config) to these data nodes without proper protection can have a negative effect on network operations. These are the subtrees and data nodes and their sensitivity/vulnerability:

```
/nd:networks/nd:network/nd:node/cl-oam:location-type/cl-oam:ipv4-
location-type/cl-oam:test-point-ipv4-location-list/cl-oam:test-
point-locations/
```

Kumar, et al. Standards Track

[Page 52]

/nd:networks/nd:network/nd:node/cl-oam:location-type/cl-oam:ipv6location-type/cl-oam:test-point-ipv6-location-list/cl-oam:testpoint-locations/

/nd:networks/nd:network/nd:node/cl-oam:location-type/cl-oam:maclocation-type/cl-oam:test-point-mac-address-location-list/cloam:test-point-locations/

/nd:networks/nd:network/nd:node/cl-oam:location-type/cl-oam:groupas-number-location-type/cl-oam:test-point-as-number-location-list/ cl-oam:test-point-locations/

/nd:networks/nd:network/nd:node/cl-oam:location-type/cl-oam:grouprouter-id-location-type/cl-oam:test-point-system-info-locationlist/cl-oam:test-point-locations/

Unauthorized access to any of these lists can adversely affect OAM management system handling of end-to-end OAM and coordination of OAM within underlying network layers. This may lead to inconsistent configuration, reporting, and presentation for the OAM mechanisms used to manage the network.

Some of the readable data nodes in this YANG module may be considered sensitive or vulnerable in some network environments. It is thus important to control read access (e.g., via get, get-config, or notification) to these data nodes. These are the subtrees and data nodes and their sensitivity/vulnerability:

/coam:cc-session-statistics-data/cl-oam:cc-ipv4-sessionsstatistics/cl-oam:cc-session-statistics/cl-oam:session-count/

/coam:cc-session-statistics-data/cl-oam:cc-ipv4-sessionsstatistics/cl-oam:cc-session-statistics/cl-oam:session-up-count/

/coam:cc-session-statistics-data/cl-oam:cc-ipv4-sessionsstatistics/cl-oam:cc-session-statistics/cl-oam:session-down-count/

/coam:cc-session-statistics-data/cl-oam:cc-ipv4-sessionsstatistics/cl-oam:cc-session-statistics/cl-oam:session-admin-downcount/

/coam:cc-session-statistics-data/cl-oam:cc-ipv6-sessionsstatistics/cl-oam:cc-session-statistics/cl-oam:session-count/

/coam:cc-session-statistics-data/cl-oam:cc-ipv6-sessionsstatistics/cl-oam:cc-session-statistics/cl-oam:session-up-count//

Kumar, et al.

Standards Track

8. IANA Considerations

This document registers URIs in the "IETF XML Registry" [RFC3688]. Following the format in [RFC3688], the following registrations have been made.

URI: urn:ietf:params:xml:ns:yang:ietf-lime-time-types Registrant Contact: The IESG. XML: N/A; the requested URI is an XML namespace.

URI: urn:ietf:params:xml:ns:yang:ietf-connectionless-oam Registrant Contact: The IESG. XML: N/A; the requested URI is an XML namespace.

This document registers two YANG modules in the "YANG Module Names" registry [RFC6020].

Name: ietf-lime-time-types Namespace: urn:ietf:params:xml:ns:yang:ietf-lime-time-types Prefix: lime Reference: RFC 8532

Name: ietf-connectionless-oam Namespace: urn:ietf:params:xml:ns:yang:ietf-connectionless-oam Prefix: cl-oam Reference: RFC 8532
